Suppose someone gives you a randomized policy π in a continuing reinforcement learning programming problem and claims it is optimal. How would you construct a deterministic policy π which is optimal?

Justify your answer.

- Is it always true that $J_{\pi}(s) \leq \max_{a} Q_{\pi}(s, a)$?
- Suppose all the rewards in a continuing reinforcement learning problem are in [0,1] and we have $\gamma=0.9$.

have $\gamma=0.9$. As in the lecture notes, we use J^* to denote the rewards-to-go under the optimal policy.

First, give an upper bound on $||J^*||_{\infty}$. Second, how many iterations does it take until we can guarantee that value iteration produces J_t with $||J_t - J^*||_{\infty} \le 0.01$ starting from $J_0 = \mathbf{0}$?

• Look at Eq. (*) in the lecture notes on Q-learning. It was derived under the assumption that the policy π is deterministic. What should the corresponding equation be when the policy is randomized?

1) I would construct a deterministic policy using temporal difference learning on the random policy. This is the best option since it is a continuous fl problem and the policy con step through the system and update the rewords-to-go until it reaches a limit. When it reaches a limit, the deterministic policy will be the Js with the largest expected rewords.

2) Prove $J_{\pi}(s) \leq \max_{a} (J_{\pi}(s,a))$:

if Qn(s,a) = ((s,a) + y Z P(s' | s,a) Jn(s')

and max Q_T(s,a) chooses the best first action

then $J_{\pi}(s) \leq \max_{a} (J_{\pi}(s,a))$

because an is determined by adding the reward of a Specific action at a state with the rewards collected by following the policy. If $J_{\pi}(s)$ is the reward collected by just following the policy, since $\max(J_{\pi}(s,a))$ chooses the optimal action, as long as the policy chooses the best action at State s, $J_{\pi}(s)$ will be equal to $\max(J_{\pi}(s,a))$. If the policy chooses a nonoptimal path initially, however, it will result in a total reward less than $\max(J_{\pi}(s,a))$ since they will follow the same policy after the determined best action.

3) a)

4) Q_{TI,t+1}(S,a) = ((S,a) + 4 \(\frac{7}{5}\) p(s'|S,a) Q_{TI,t}(s', TI(s'))
Randomized:

 $Q_{\pi,t+1}(s,a) = \sum_{\alpha} \pi(\alpha|s) r(s,a) + \sum_{\alpha'} P(s'|s,a) \sum_{\alpha'} Q_{\pi,t} (s',\alpha') \pi(\alpha'|s')$

 Consider an MDP with two states, A and B. In A, there are two actions you can take. Action 1 keeps you in state A, with a reward of one.
 Action 2 moves you to B, with a reward of zero. In state B, there is only

one action to take, which keeps you in B with a reward of 2.

You want to use temporal difference learning to evaluate the rewardsto-go of the "choose at random" policy.

You generate the following two sample paths:

$$s_0 = A, a_0 = 1, s_1 = A, a_1 = 2, s_2 = B$$

 $s_0 = A, a_0 = 2, s_1 = B, a_1 = 1, s_2 = B, a_2 = 1, s_3 = B$

Use temporal difference learning to come up with estimates of the rewards-to-go from both states starting from [16,16].

a)
$$S_1 = A$$
 $a_1 = 1$

$$S_2 = A$$
 $a_1 = 2$

$$S_3 = B$$

$$\int_{2}^{z} \left[16 + \frac{1}{1} \left(1 + \frac{1}{2} (16) - 16 \right) \right] = \left[16 + \left(1 + 8 - 16 \right) \right] \\
= \left[16 + \left(-7 \right) \right] = \left[9 \right] \\
= \left[16 + \left(-7 \right) \right] = \left[9 \right]$$

$$J_{3} = \begin{bmatrix} 9 + \frac{1}{2}(0 + \frac{1}{2}(16) - 9) \\ 16 \end{bmatrix} = \begin{bmatrix} 9 + \frac{1}{2}(8 - 9) \\ 16 \end{bmatrix} = \begin{bmatrix} 8.5 \\ 16 \end{bmatrix}$$

b)
$$S_{1} = A \quad \alpha_{1} = 2$$

 $S_{2} = B \quad \alpha_{2} = 1$
 $S_{3} = B \quad \Omega_{3} = 1$
 $S_{4} = B$

$$J_{2} = \begin{bmatrix} 16 + \frac{1}{1}(0 + \frac{1}{2}(16) - 16) \\ 16 \end{bmatrix} = \begin{bmatrix} 16 + (8 - 16) \\ 16 \end{bmatrix} = \begin{bmatrix} 8 \\ 16 \end{bmatrix}$$

$$\overline{J}_{3} = \begin{bmatrix} 8 \\ 16 + \frac{1}{2}(2 + \frac{1}{2}(16) - 16) \end{bmatrix}^{2} = \begin{bmatrix} 8 \\ 16 + \frac{1}{2}(2 + 8 - 16) \end{bmatrix}$$

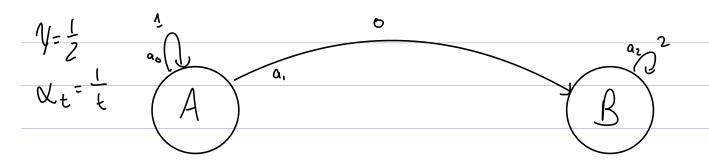

$$= \begin{bmatrix} 8 \\ 16 + \frac{1}{2}(-6) \end{bmatrix}^{2} = \begin{bmatrix} 8 \\ 13 \end{bmatrix}$$

$$J_{4} = \begin{bmatrix} 8 \\ (3 + \frac{1}{3}(2 + \frac{1}{2}(13) - 13) \end{bmatrix}^{2} = \begin{bmatrix} 8 \\ 13 + \frac{1}{3}(2 + \frac{13}{2} - 13) \end{bmatrix}^{2}$$

$$= \begin{bmatrix} 8 \\ 13 + \frac{1}{3}(-\frac{9}{2}) \end{bmatrix}^{2}$$

$$= \begin{bmatrix} 8 \\ 13 - \frac{3}{2} \end{bmatrix}^{2} = \begin{bmatrix} 23 \\ 23 \end{bmatrix}^{2}$$

Consider an MDP with two states, A and B. In A, there are two
actions you can take. Action 1 keeps you in state A, with a reward of
one. Action 2 moves you to B, with a reward of zero. In state B, there
is only one action to take, which keeps you in B with a reward of 2.

lst iteration.

$$Q_{2}(A,1) = 16 + \frac{1}{1}(1 + \frac{1}{2} \max(Q_{1}(A,1), Q_{1}(A,2)) - 16)$$

$$= 16 + \frac{1}{1}(1 + \frac{1}{2}(16) - 16)$$

$$= 16 + \frac{1}{1}(1 + 8 - 16) = 16 - 7 = 9$$

$$Q_2 = \begin{bmatrix} 9 \\ 16 \end{bmatrix}$$

2nd

iteration:
$$(2_3(A,2) = 16 + \frac{1}{2}(0 + \frac{1}{2} \max(Q_2(B,1)) - 16)$$

= $16 + \frac{1}{2}(\frac{1}{2}(16) - 16)$
= $16 + \frac{1}{2}(8 - 16) = 12$

iteration:
$$Q_4(B,1) = |6+\frac{1}{3}(2+\frac{1}{2} \max(Q_3(B,1))-|6|)$$

 $= |6+\frac{1}{3}(2+\frac{1}{2}(16)-16)$
 $= |6+\frac{1}{3}(-6)$
 $= |6-2=14$

$$Q_{4} = \begin{bmatrix} 9 \\ 12 \\ 14 \end{bmatrix}$$
